

# Strong law of large numbers (First version)

Theorem: Let  $X_1, X_2, \dots$  be a sequence of independent random variables. Suppose that  $\mathbb{E}(X_i) = 0$  and  $\mathbb{E}(X_i^4) \leq K$  for all  $i$  and some uniform constant  $K > 0$ . Then,

$$\frac{X_1 + X_2 + \dots + X_n}{n} \rightarrow 0 \text{ almost surely.}$$

Proof: We consider the fourth moment.

$$\begin{aligned} S_n &= X_1 + X_2 + \dots + X_n \\ \mathbb{E}(S_n^4) &= \mathbb{E}(X_1 + \dots + X_n)^4 \\ &= \mathbb{E}(X_1^4) + \dots + \mathbb{E}(X_n^4) \\ &\quad + 4(\mathbb{E}(X_1 X_2^3) + \mathbb{E}(X_1^3 X_2) + \dots) \\ &\quad + 6(\mathbb{E}(X_1^2 X_2^2) + \dots) \\ &\quad + 12(\mathbb{E}(X_1^2 X_2 X_3) + \dots) \\ &\quad + 24(\mathbb{E}(X_1 X_2 X_3 X_4) + \dots) \end{aligned}$$

We can use independence for mixed terms such as  $\mathbb{E}(X_1^2 X_2 X_3) = \mathbb{E}(X_1^2) \mathbb{E}(X_2) \mathbb{E}(X_3) = 0$ .

We are left with terms of form

1)  $\mathbb{E}(X_i^4)$  but they are bounded by  $K$ .

2)  $\mathbb{E}(X_i^2 X_j^2) \leq \sqrt{\mathbb{E}(X_i^4) \mathbb{E}(X_j^4)} \leq K$  for all  $i, j$ .

by Cauchy-Schwarz.

$$\text{So, } \mathbb{E}(S_n^4) \leq nK + G \cdot \binom{n}{2} K$$

$$= K(n + 3n(n-1)) = K_n(3n-2) \leq 3Kn^2$$

$$\text{So } \mathbb{E}\left(\left(\frac{S_n}{n}\right)^4\right) \leq \frac{3K}{n^2}$$

$$\Rightarrow \mathbb{E}\left(\sum_{n=1}^{\infty} \left(\frac{S_n}{n}\right)^4\right) \leq 3K \sum_{n=1}^{\infty} \frac{1}{n^2} < \infty.$$

So with probability 1,  $\sum_{n=1}^{\infty} \left(\frac{S_n}{n}\right)^4$  converges

and with probability 1  $\frac{S_n}{n} \rightarrow 0$ .  $\square$

Special case: If  $X_1, X_2, \dots$  are independent and identically distributed with  $\mathbb{E}(X_i^4) < \infty$ ,

then  $Y_i = X_i - \mathbb{E}(X_i)$  has expectation 0.

$Y_1, Y_2, \dots$  satisfy the conditions above and

$$\frac{Y_1 + \dots + Y_n}{n} \rightarrow 0, \quad \frac{(X_1 - m) + \dots + (X_n - m)}{n} \rightarrow 0$$

and  $\frac{X_1 + X_2 + \dots + X_n}{n} \rightarrow m$ , where  $m = \mathbb{E}(X_i)$ .

We can derive the distance to  $\mu = E(X)$  by means of Chebyshev's inequality.

$$P(|X - \mu| \geq c) \leq \frac{\text{Var}(X)}{c^2}.$$

It is a special case of Markov's inequality:

$$P(|X - \mu|^2 \geq c) \leq \frac{1}{c^2} E(|X - \mu|^2) = \frac{\text{Var}(X)}{c^2}.$$

Applying this to  $S_n = X_1 + X_2 + \dots + X_n$ , where  $X_1, X_2, \dots$  are independent identically distributed (i.i.d.) random variables with  $\mu = E(X_i)$  and  $\sigma^2 = \text{Var}(X_i) < \infty$  gives

$$E(S_n) = E(X_1) + \dots + E(X_n) = n\mu,$$

$$\text{Var}(S_n) = \text{Var}(X_1) + \dots + \text{Var}(X_n) = n\sigma^2 \text{ by independence}$$

$$\text{Further } \text{Var}\left(\frac{S_n}{n}\right) = \text{Var}\left(\frac{S_n - n\mu}{n}\right) = \frac{n\sigma^2}{n^2} = \frac{\sigma^2}{n}$$

$$\text{So } P\left(\left|\frac{1}{n}S_n - \mu\right| \geq c\right) \leq \frac{\sigma^2}{n \cdot c^2} \rightarrow 0 \text{ as } n \rightarrow \infty$$

Since  $c$  was arbitrary we have

$$\frac{S_n}{n} \rightarrow \mu \text{ in probability.}$$

# Conditional Expectation

Simple Example: Throw a die. All outcomes  $1, 2, \dots, 6$  are equally likely.

Write  $X$  for the r.v. that gives the outcome.

We have  $P(X \leq 3) = \frac{3}{6} = \frac{1}{2}$ .

Suppose we additionally know the outcome is even or odd.

The conditional probabilities of the event  $\{X \leq 3\}$  are

$$P(X \leq 3 \mid X \text{ odd}) = \frac{P(\{X \leq 3\} \cap \{X \text{ odd}\})}{P(\{X \text{ odd}\})} = \frac{2}{3}$$

$$P(X \leq 3 \mid X \text{ even}) = \frac{P(\{X \leq 3\} \cap \{X \text{ even}\})}{P(\{X \text{ even}\})} = \frac{1}{3}$$

We can also obtain conditional expectations:

$$E(X \mid X \text{ even}) = \frac{2+4+6}{3} = 4$$

$$E(X \mid X \text{ odd}) = \frac{1+3+5}{3} = 3.$$

Generally, we define conditional expectations with respect to  $\sigma$ -algebras

Definition (Theorem): Let  $(\Omega, \mathcal{F}, P)$  be a probability space and  $\mathcal{G} \subseteq \mathcal{F}$  a sub  $\sigma$ -algebra. Let  $X$  be an integrable random variable.

Then exists a random variable  $Y = Y(\omega)$  with the following properties:

- (1)  $Y$  is  $\mathcal{G}$ -measurable
- (2)  $Y$  is integrable
- (3) For all  $G \in \mathcal{G}$ :  $\int_G Y dP = \int_G X dP$

Moreover  $Y$  is almost surely unique.

For any  $Y, Y'$  satisfying (1)-(3),  $P(Y=Y')=1$ .

This random variable is called the conditional expectation of  $X$  w.r.t.  $\mathcal{G}$  and we write  $Y(\omega) = \underline{E}(X | \mathcal{G}) (= E(X | \mathcal{G})(\omega))$ .

If  $\mathcal{G}$  is generated by random variables we write

$$E(X | \mathcal{Z}) \text{ instead of } E(X | \sigma(\mathcal{Z}))$$
$$E(X | \mathcal{Z}_1, \mathcal{Z}_2, \dots, \mathcal{Z}_n) \text{ --- } E(X | \sigma(\mathcal{Z}_1, \dots, \mathcal{Z}_n)).$$

Example: In our die throwing example

$$\mathcal{F} = \mathcal{P}(\{1, \dots, 6\}), \quad \mathcal{G} = \{\emptyset, \{1, 3, 5\}, \{2, 4, 6\}, \Omega\}$$

$\mathcal{G}$  measurability  $\Rightarrow Y$  must be constant on  $\{1, 3, 5\}$  and  $\{2, 4, 6\}$ , respectively.

$$\text{Say } Y(\omega) = \begin{cases} a & \text{for } \omega \in \{1, 3, 5\} \\ b & \text{for } \omega \in \{2, 4, 6\} \end{cases}.$$

$$1) \int_{\emptyset} Y dP = \int_{\emptyset} X dP \quad \text{Trivial } 0=0.$$

$$2) \int_{\{1, 3, 5\}} Y dP = \int_{\{1, 3, 5\}} X dP$$

$$\Rightarrow a P(\{1, 3, 5\}) = 1 P(\{1\}) + 3 P(\{3\}) + 5 P(\{5\})$$

$$\Rightarrow \frac{1}{2} a = \frac{1+3+5}{6} \Rightarrow a = 3$$

$$(3) \int_{\{2,4,6\}} Y \, dP = \int_{\{2,4,6\}} X \, dP$$

$$\Rightarrow \frac{1}{2} b = \frac{2+4+6}{6} \Rightarrow b = 4.$$

$$(4) \int_{\Omega} Y \, dP = \int_{\Omega} X \, dP$$

Sum of (2) & (3) so also satisfied.

Remark: The "ordinary" expectation is the special case  $\mathcal{G} = \{\emptyset, \Omega\}$ . Then  $Y$  is constant on  $\Omega$  and

$$\int_{\emptyset} X \, dP = \int_{\emptyset} Y \, dP \quad (\text{trivial})$$

$$\int_{\Omega} X \, dP = \int_{\Omega} Y \, dP \Rightarrow Y(\omega) = \int_{\Omega} X \, dP = E(X).$$

We may interpret  $\sigma$  algebras as "knowledge" of an event and will investigate

sequences  $X_1, X_2, \dots$  of integrable random variables:

Central theme:

Def<sup>n</sup> Let  $X_1, X_2, \dots$  be integrable random variables. The sequence is a martingale

if  $\mathbb{E}(X_{n+1} \mid \sigma(X_1, X_2, \dots, X_n)) = X_n$ .

Informally, the expectation of the  $(n+1)$ -th random variable conditioned on "knowing" outcomes  $X_1, \dots, X_n$  is equal to the last observed value.

Properties of conditional expectation:

Th<sup>m</sup> We have

$$(1) \mathbb{E}(\mathbb{E}(X \mid \mathcal{G})) = \mathbb{E}(X)$$

(2) If  $X$  is  $\mathcal{G}$  measurable, then  $\mathbb{E}(X \mid \mathcal{G}) = X$  a.s.

(3) Linearity:  $\mathbb{E}(aX + bY \mid \mathcal{G}) = a\mathbb{E}(X \mid \mathcal{G}) + b\mathbb{E}(Y \mid \mathcal{G})$  a.s.

(4) Positivity: If  $X \geq 0$  a.s. then  $\mathbb{E}(X \mid \mathcal{G}) \geq 0$  a.s.

Proof:

(1) Since  $\Omega \in \mathcal{G}$ , we have

$$E(E(X|\mathcal{G})) = \int_{\Omega} E(X|\mathcal{G}) dP = \int_{\Omega} X dP = E(X)$$

(2)  $X$  satisfies all conditions in definition (theorem)

(3) Note that  $a E(X|\mathcal{G}) + b E(Y|\mathcal{G})$

is  $\mathcal{G}$ -measurable. The condition then follows by linearity of integration.

(4) Suppose  $Y = E(X|\mathcal{G})$  is negative with positive probability:  $P(Y < 0) > 0$ .

Then  $\exists n$  s.t.  $P(Y \leq -\frac{1}{n}) > 0$ . This is hence a  $\mathcal{G}$  measurable set and

$$\underbrace{\int_{\{Y \leq -\frac{1}{n}\}} Y dP}_{\leq -\frac{1}{n} P(\{Y \leq -\frac{1}{n}\}) < 0} = \underbrace{\int_{\{Y \leq -\frac{1}{n}\}} X dP}_{\geq 0}$$

A contradiction.

□

Results on convergence carry over: non-neg.

Th<sup>m</sup> (1) If  $X_1, X_2, \dots$  is a sequence of random variables such that  $X_n \uparrow X$ , then we also have  $E(X_n | \mathcal{G}) \uparrow E(X | \mathcal{G})$ . (MCT)

(2) If  $X_1, X_2, \dots$  is a sequence of random variables s.t.  $|X_n| \leq Y$  for some integrable  $Y$ , and  $X_n \rightarrow X$ , then also  $E(X_n | \mathcal{G}) \rightarrow E(X | \mathcal{G})$ . (DCT)

(3) If  $X_1, X_2, \dots$  is any sequence of non-negative random variables, then

$$E\left(\liminf_{n \rightarrow \infty} X_n \mid \mathcal{G}\right) \leq \liminf_{n \rightarrow \infty} E(X_n \mid \mathcal{G}). \quad (\text{Fatou})$$
